Status: current

Deployment Guide - Overview and Prerequisites

This guide describes how to deploy the platform to a staging or production environment.

Prerequisites: Docker 24 or later, access to the container registry, and a valid deployment token.

Deployment Guide - Deployment Steps

1. Pull the latest image from the registry.
2. Run database migrations.
3. Deploy using the rolling-update strategy with a maximum of 25 percent of pods unavailable at a time.
4. Verify that the health endpoint returns a 200 response.

Deployment Guide - Rollback Procedure

If health checks fail after deployment, roll back immediately using the 'deploy rollback' command with the previous release id. Rollback must be completed within 15 minutes of detecting a failure.

Deployment Guide - Health Checks

The `/health` endpoint checks database connectivity, cache connectivity, and background worker status. A 503 response indicates a dependency failure.
